Deploying a Zoho Creator Application from Development to Production

Project: Job Application Management System

Aim

To understand the release process for the Job Application Management System in Zoho Creator, including testing, deployment readiness, permissions, connection configuration, data handling, and post-deployment verification.

Introduction

The Job Application Management System contains candidate/application fields, reports, dashboards, and workflows. Changes should be tested before the app is shared with recruiters or other users. Separating development and production reduces the chance that unfinished changes affect live application records. The availability of multiple environments depends on the Zoho Creator plan.

Environments and Their Purpose

Environment	Purpose in this project	Typical users
Development	Build forms, fields, workflows, Deluge validation, reports and dashboard.	Developer
Stage / Testing	Test sample applications, required fields, salary validation, reports and role permissions.	Developer / tester
Production	Live version used by authorized recruiters or administrators to manage applications.	Authorized users

Deployment Procedure

1. Prepare the development version. Review the Job Application form fields: Name, Email, Phone, Job Role, application date, Skills, Resume, Experience, Address and Expected Salary. Confirm field names and required-field settings.

2. Test workflows and validation. Test the Expected Salary validation with valid and invalid values. Submit a test application and confirm the successful-submission workflow behaves as expected.

3. Verify reports and dashboard. Check the expected-salary chart, pie chart, KPI panels and any application-count reports against the records entered for testing.

4. Review access permissions. Confirm only authorized users can view, add, edit or export candidate details. Review recruiter/admin roles if configured.

5. Check connections and integrations. Confirm any configured email, API or other connection is authorized in the target environment. If the current plan or connection limit blocks a connection, document the limitation instead of claiming the integration works.

6. Deploy or publish if available. Use the deployment/environment options provided by the account. If Stage or Production environments are not available on the current subscription, document that limitation and demonstrate the tested development app without claiming a production deployment.

7. Post-deployment verification. After publishing, open the app using an authorized test account and verify form submission, validation, reports, permissions and connections. Keep a backup/export of important records where supported.

Project-Specific Pre-Deployment Checklist

Check	Verification	Status
Form fields	All application fields display correctly and required fields are configured.	Pending / passed
Salary validation	Invalid salary input is rejected; valid input is accepted.	Pending / passed
Submission workflow	Successful submission action runs as intended.	Pending / passed
Dashboard and reports	Charts and KPI values match test records.	Pending / passed
Roles and permissions	Users have only the access required for their roles.	Pending / passed
Connections	Connections are authorized and tested in target environment.	Pending / restricted
Backup and release notes	Important data backed up; changes documented.	Pending / passed

Important Deployment Concepts

• **Version history:** Record what changed and when a version was released.

• **Data migration:** Application structure and existing records may not move together; export/import or other supported migration steps may be needed.

• **Connections:** API/OAuth connections may need separate authorization in the target environment.

• **Permissions:** Recheck recruiter/admin access after publishing.

• **Rollback:** Keep a known-good version or data backup so recovery can be planned if a release causes problems.

Result

A project-specific deployment plan and pre-deployment checklist have been prepared for the Job Application Management System. The live deployment status must be recorded only after the available environment and publishing options have been tested. If the account plan restricts multi-environment deployment or connections, that restriction is documented accurately.

Viva Focus

Be prepared to explain development vs stage vs production, why testing is performed before release, why records and application structure may migrate separately, why connections need re-authorization, and how permissions and rollback reduce deployment risk.

Note: This report adapts the supplied EXP-11 topic to the Job Application Management System. It is not a copy of the reference PDF; project fields, workflows, dashboard checks, and connection-limit caveats have been customized.
